**COMSOL
CONFERENCE
2018 LAUSANNE**

Thawing of large tuna fishes for the canning industry

- energy-hungry industrial process (air or water immersion techniques)
- Long thawing times
- Thermal heterogeneities (core vs. surface)

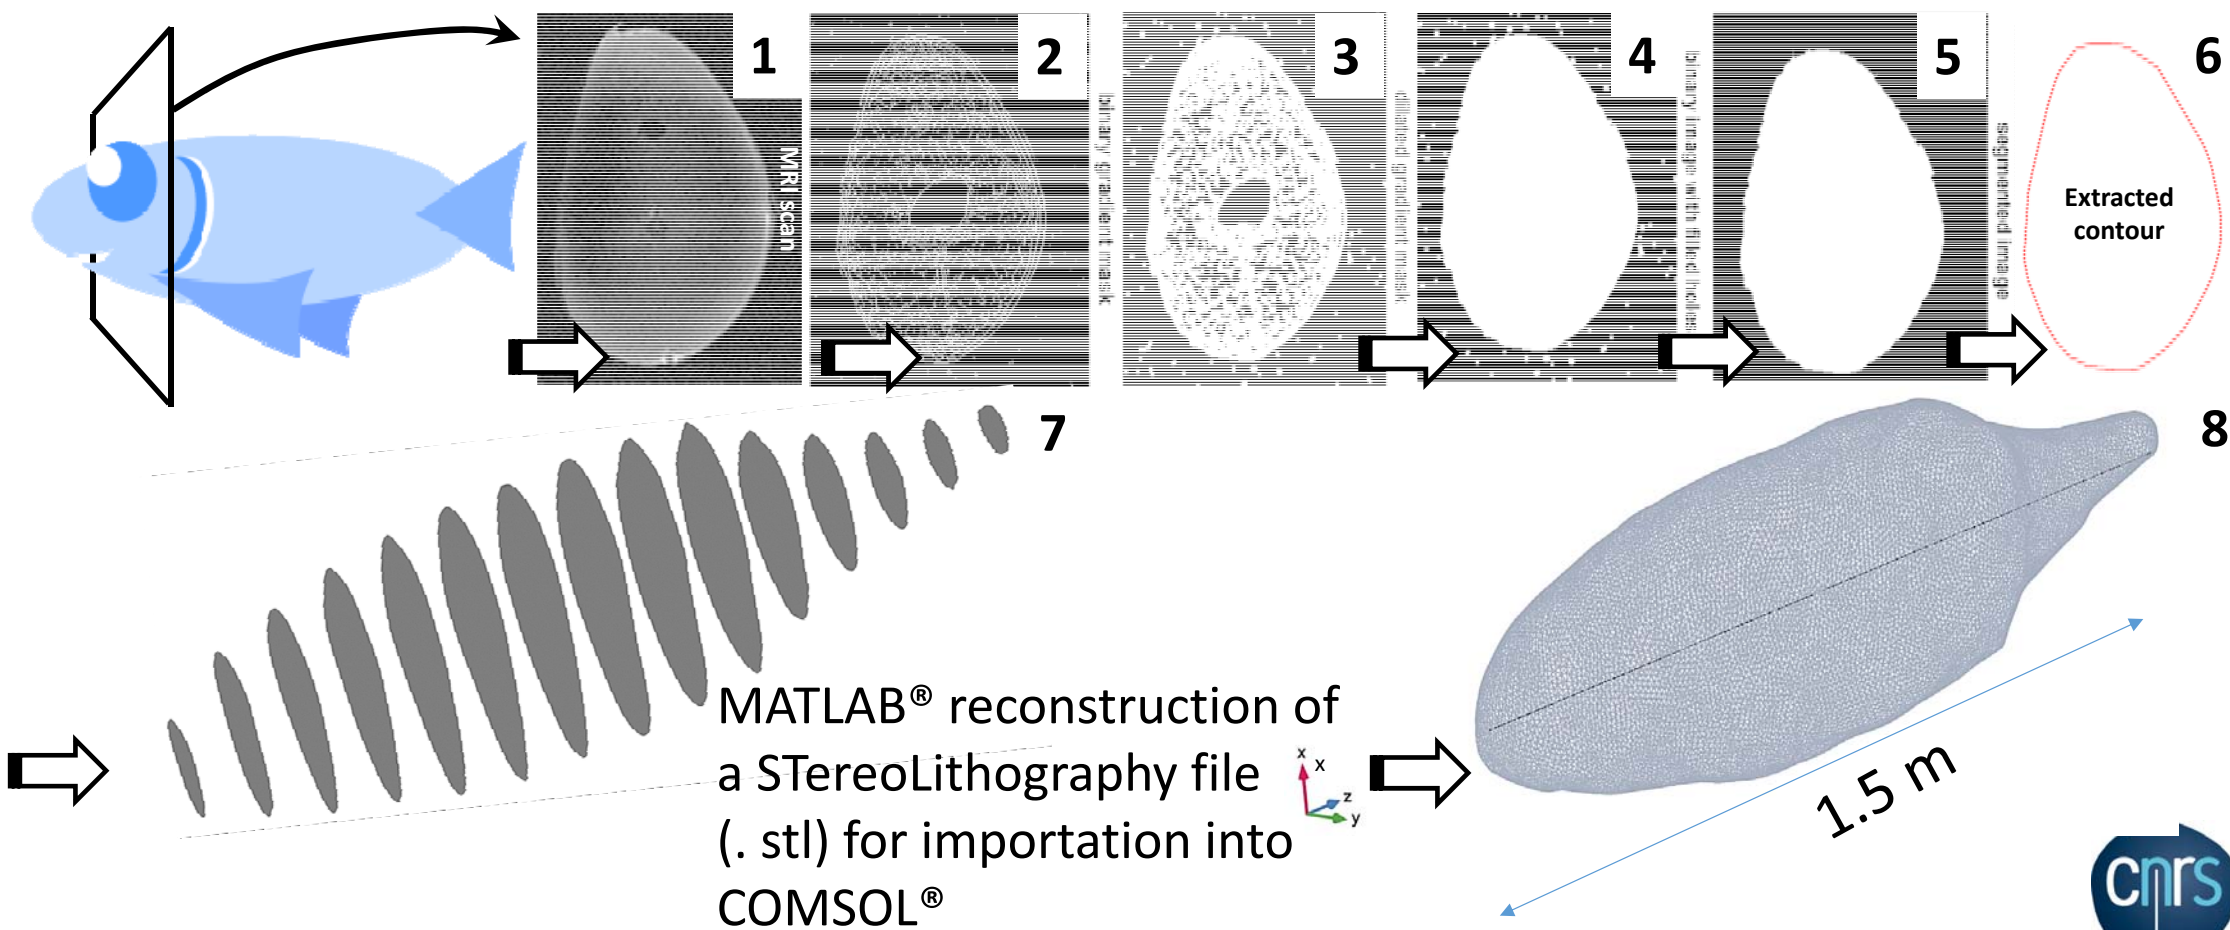

Need to predict accurately the temperature distribution inside the product (hot and cold spots)

=> Ensuring microbial safety

=> Reduction of fluid and energy consumption

MRI scans and image processing for COMSOL® modelling

Mesh generation

1 312 939 tetrahedral elements

Element sizes

→ 2.25 mm min.

→ 10 mm max.

Modelling heat transfer during thawing: *Apparent specific heat approach*

$$\rho(T)Cp_{app}(T) \frac{\partial T}{\partial t} = \nabla \cdot (\lambda(T)\nabla T)$$

Boundary condition

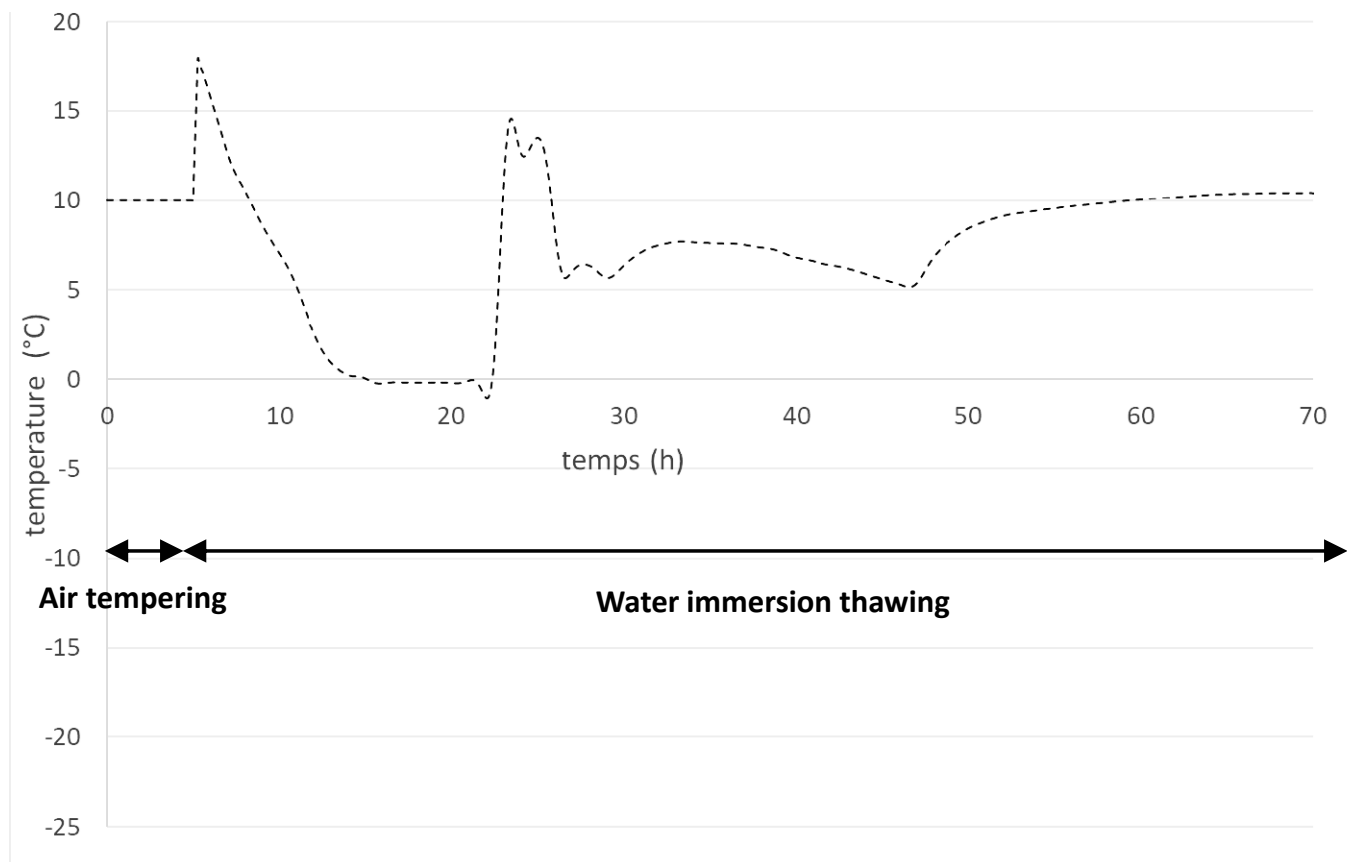

$$-\vec{n}(-\lambda\nabla T) = -h(T - T_{ext})$$

- Uniform heat transfer coefficient (h) around the external surface of the product
- Time-varying external temperature of the fluid

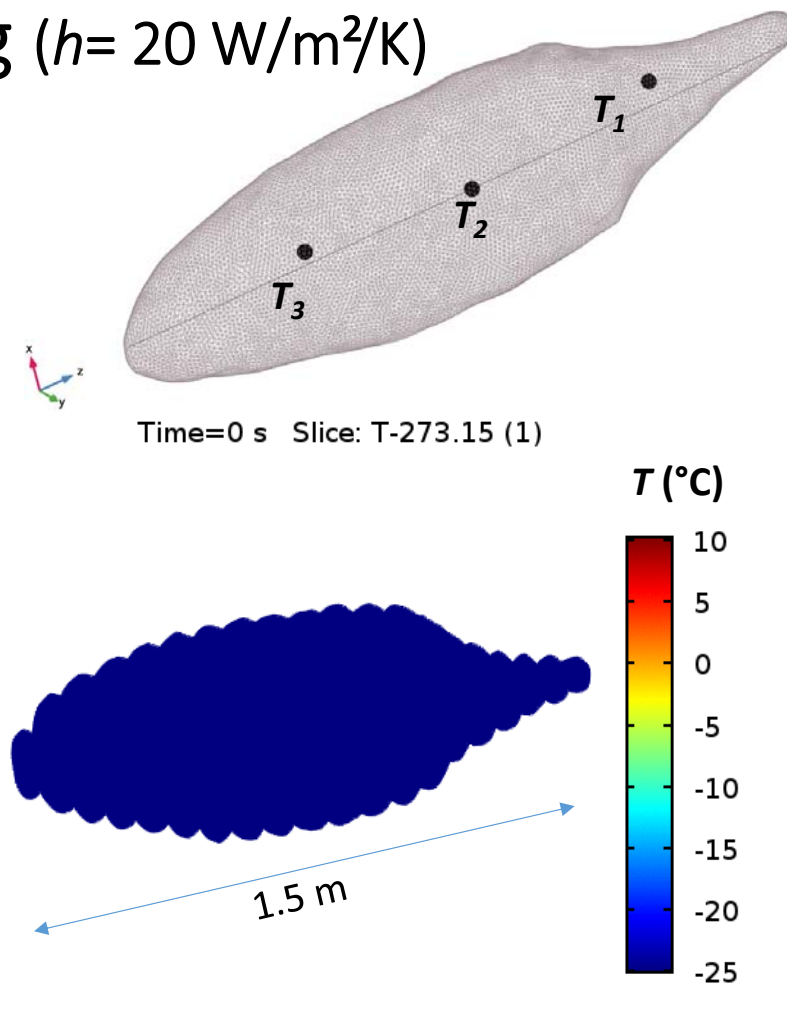

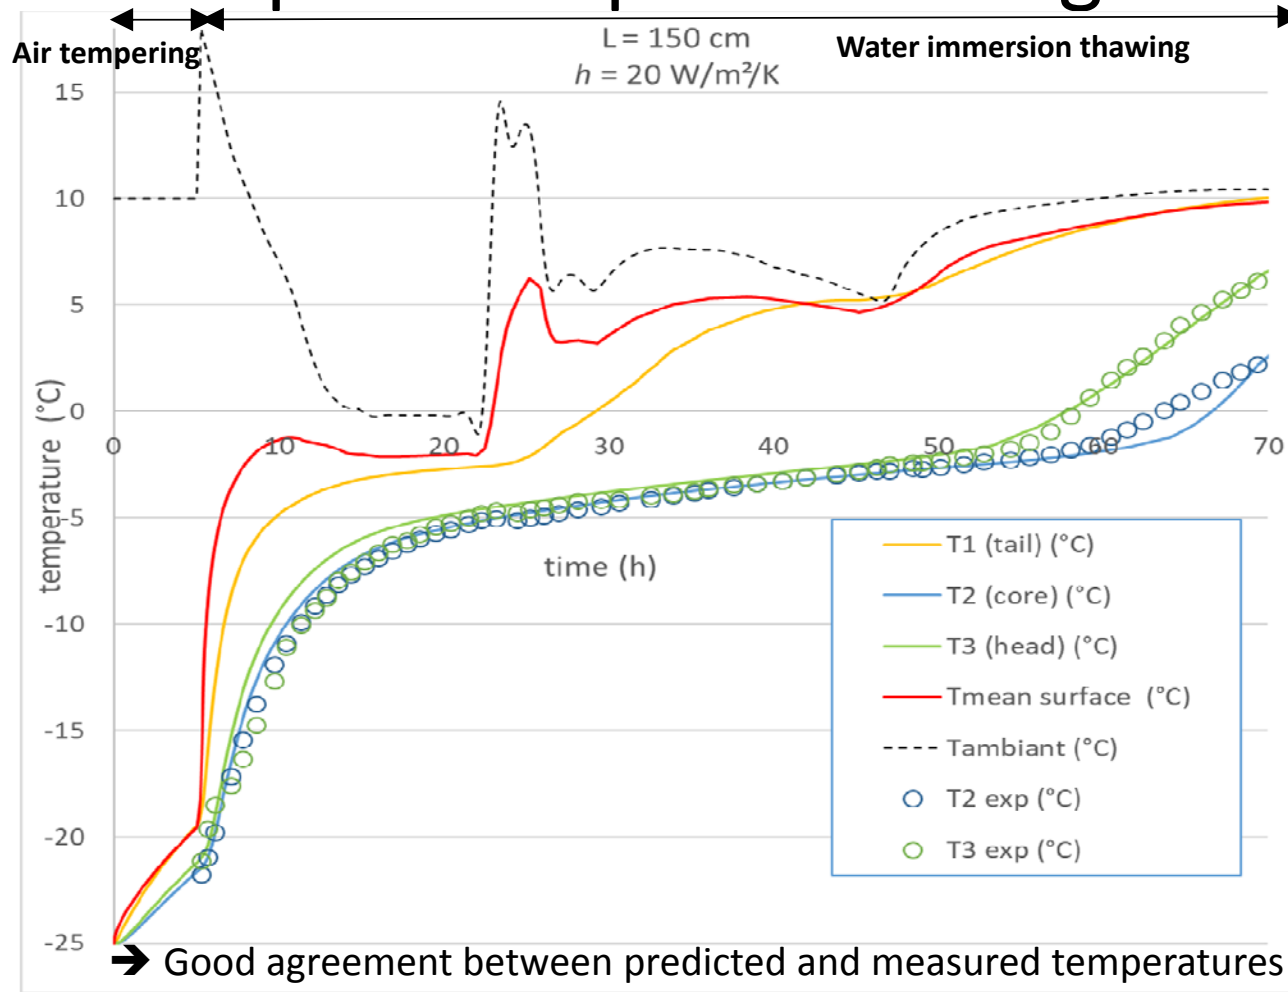

Boundary condition

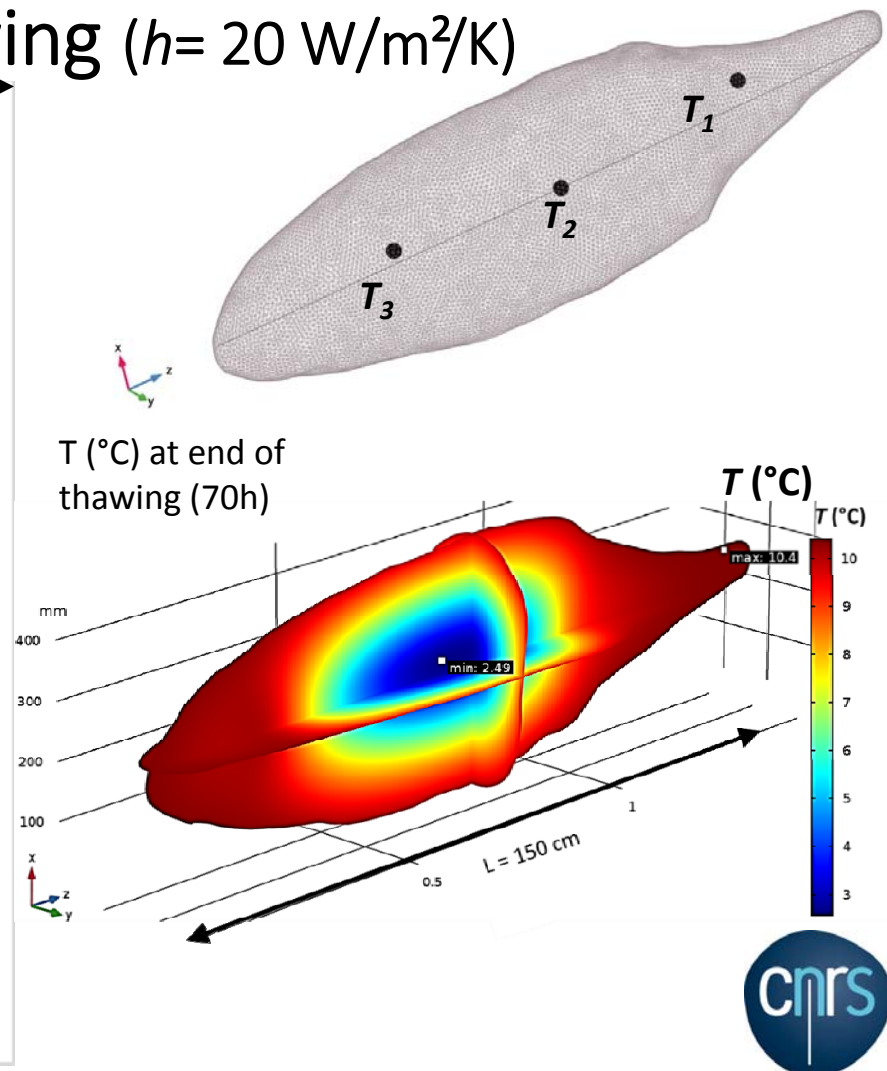

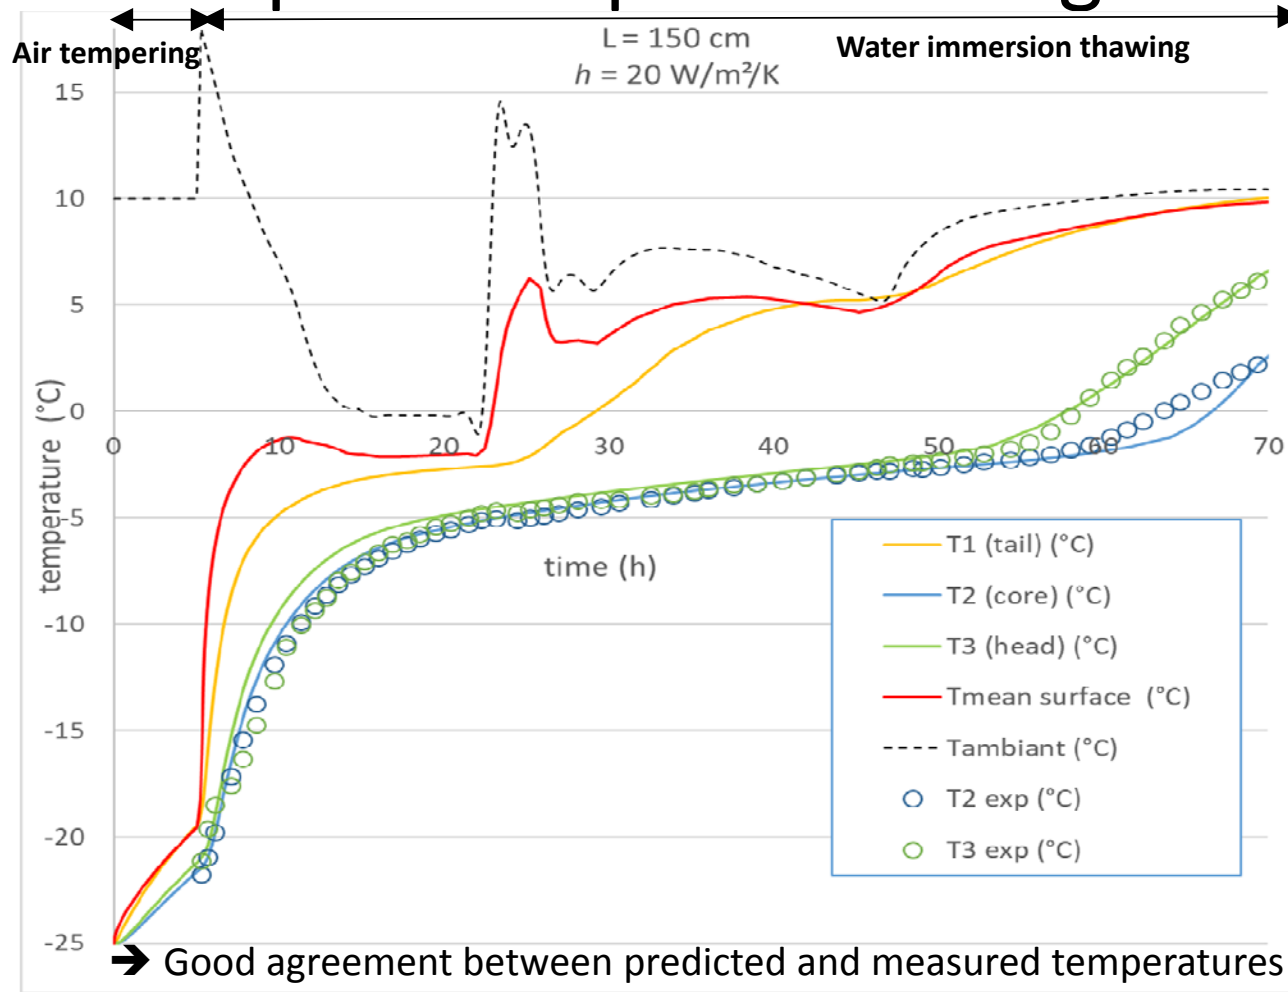

- Time-varying external temperature of the fluid (air and water)

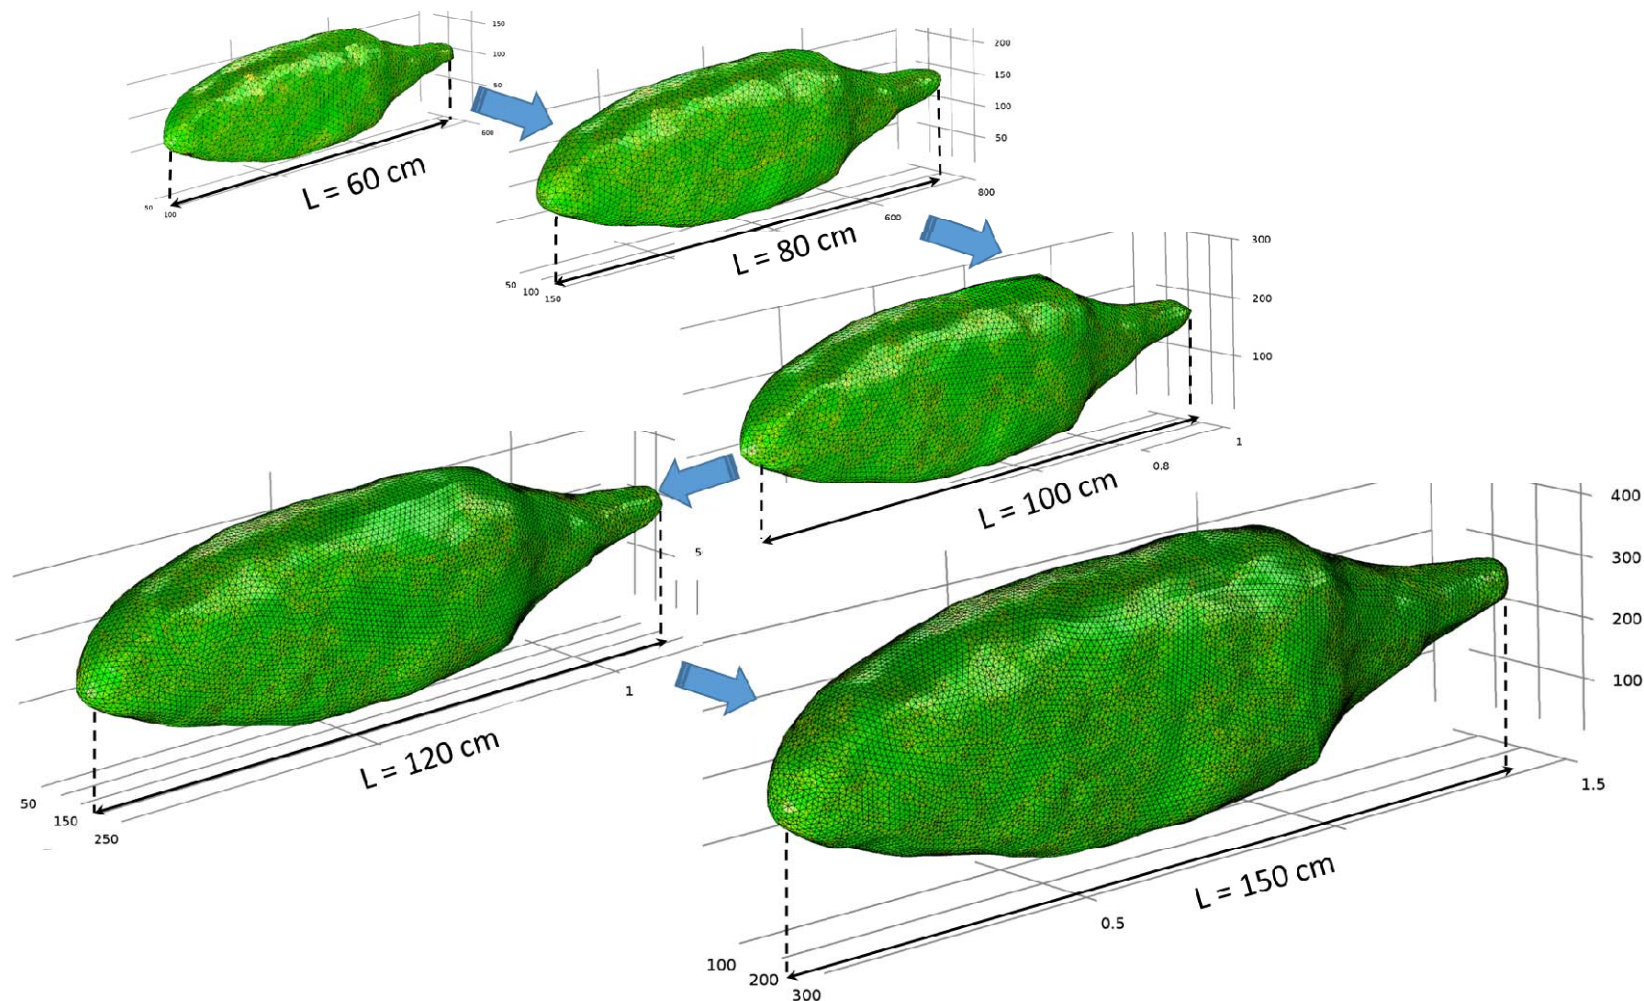

Temperature profile during thawing ($h = 20 \text{ W/m}^2/\text{K}$)

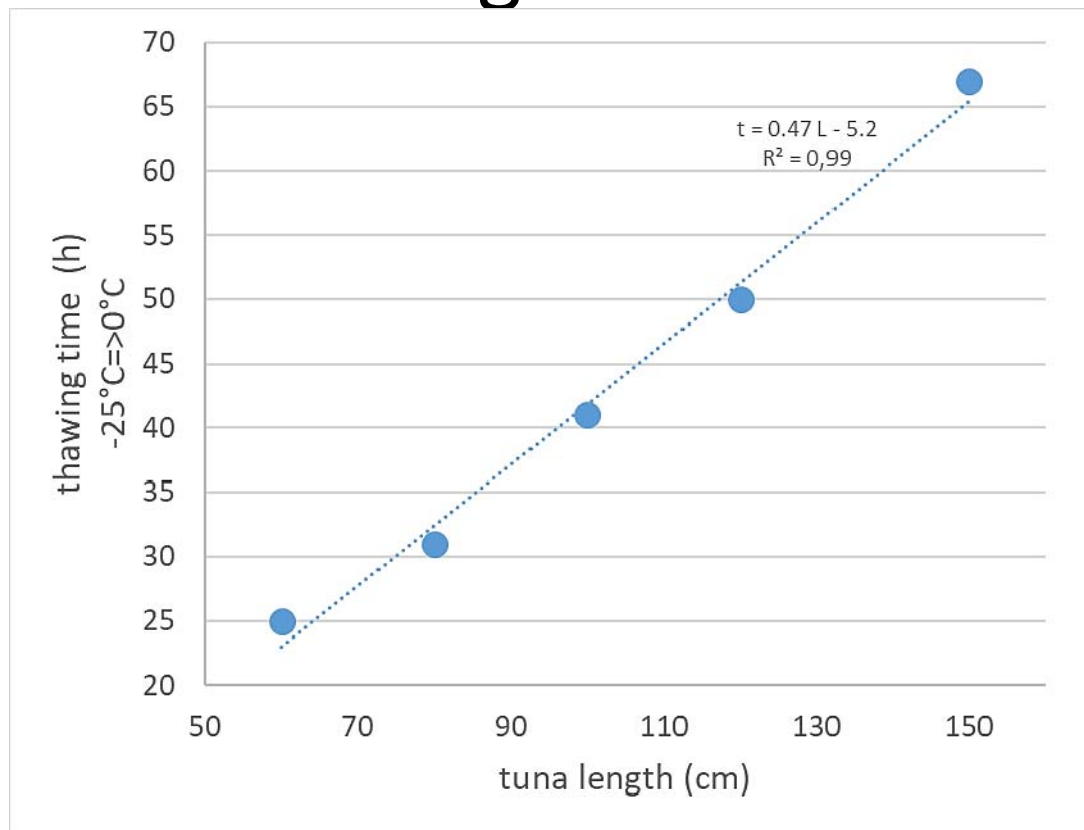

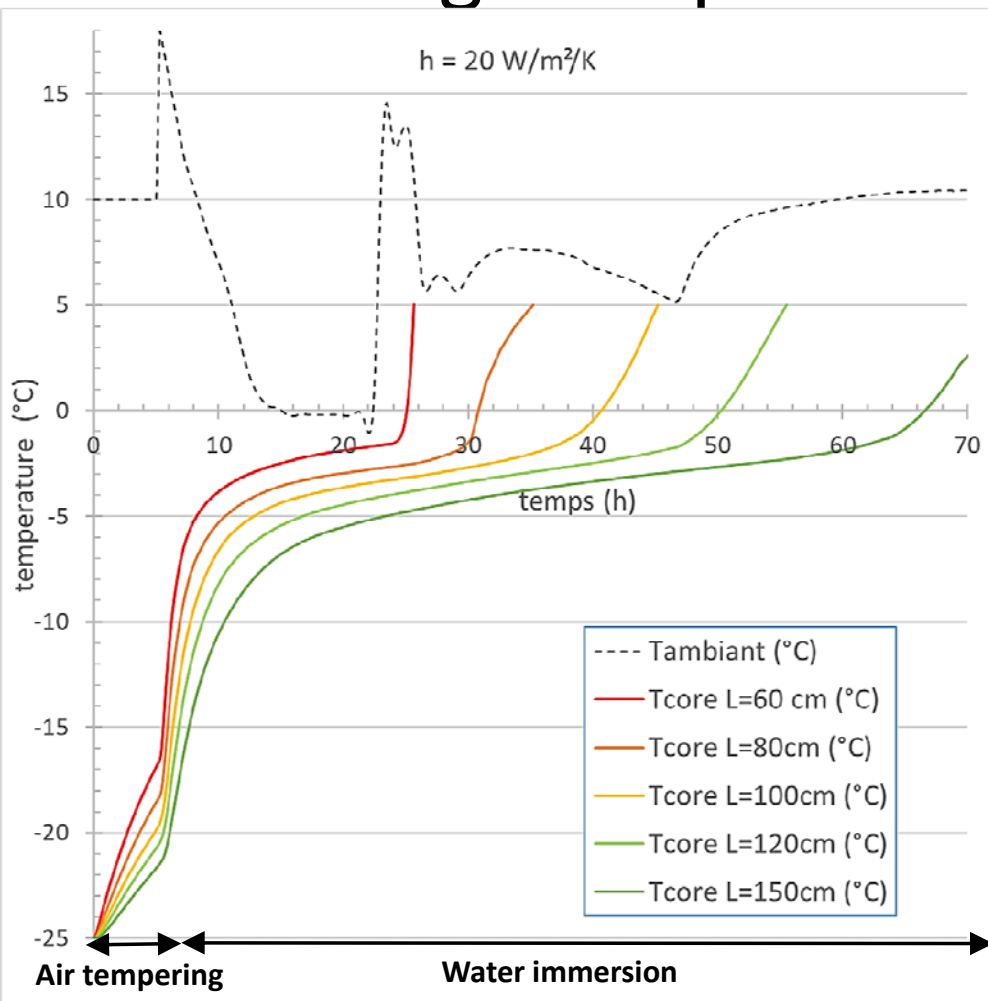

Temperature profile during thawing ($h = 20 \text{ W/m}^2/\text{K}$)

Generation of different-sized fishes

Thawing time prediction vs. tuna length

➔ Linear increase of thawing time vs. tuna length

Modelling thawing of real tuna fishes:

- Successful reconstruction of the real geometry from MRI scanning techniques
- Good prediction of inner temperatures of the fish during the process (tempering + thawing)
- Extrapolation of results for different sized-products
- Future directions of the work will include the influence of the external temperature evolution on the thawing time prediction.

Thank you for your attention
